## Project 2 Report

GitHub Copilot made it straightforward to generate the bulk of the code for this project. I simply copied the project requirements from the assignment PDF into VS Code, and typed in a blank “def” statement for each function. Copilot filled in the rest.

A challenge faced was making the different functions work together. Although Copilot was useful in generating functions for starting the game, taking the forest path, and taking the cave path, I had to add in my own print statements to indicate that the selected path led to a victory or a loss. Additionally, the final result led to a lot of condensed text in the output, when I would have preferred newlines between important events. The changes I had to make for the victory and loss situation indicates to me that Copilot is useful for large blocks of code, but not as useful when making tiny edits inside of a function. Possibly the results could have been different if I had included more information from instructions at the top of the file, and Copilot would have figured out the context from that.

Enhancements and modifications I had to make in the generated code were indicating that a certain choice in the forest and cave paths led to a victory or a loss. Copilot left room for me to add this in, and as it was a small change it is not greatly practical to auto-generate code here, as Copilot may introduce more logic than necessary that causes the other functions to break. I also added the print statement at the beginning as the problem statement indicated to confirm a working setup, and as this was only one statement it was simpler for me to add it than to ask Copilot to do so.
